

The Date and Time Model

A Date is one number. Everything else (the year, the string, the time zone) is presentation.

The one idea to hold on to

The stored number never has a time zone.
A zone appears only when you ASK for a human-readable part, and it is whatever zone the machine reading it is set to.
So the same Date shows a different hour in London and in New York, and that is correct.

Formatting for people: use Intl, not string surgery

```
new Intl.DateTimeFormat('en-GB', {
  dateStyle: 'long', timeStyle: 'short',
  timeZone: 'Europe/London'
}).format(date)
Intl.NumberFormat and Intl.RelativeTimeFormat
handle currency and "3 days ago" the same way.
```

Store and send UTC, an ISO string or a number; convert to local only at the moment you display. Months are ZERO-based (0 is January) though days of the month are not. Date has no date-only type and no proper zone support, which is why the Temporal API is on the way; until then, reach for a library for anything beyond simple formatting.
