

Hoisting and the Temporal Dead Zone

Declarations are registered before the code runs. What differs is whether you may touch them yet.

var	let / const	function declaration
console.log(x); // undefined	console.log(y); // ReferenceError	greet(); // works
var x = 1;	let y = 1;	function greet() { }
Hoisted AND pre-initialized to undefined. No error, just a confusing value, which is why modern code does not use var.	Hoisted but NOT initialized. The gap between the two is the Temporal Dead Zone: the name exists, using it throws.	Fully hoisted, body and all. A function stored in a let or const follows that variable's rules instead, so it is NOT callable early.

The practical rule is simple: const by default, let when you must reassign, var never. Declare things before you use them and the TDZ never fires. Note that const freezes the BINDING, not the value: the contents of a const object can still change.
