

The TypeScript Pipeline

Types are checked, then ERASED. Nothing you write in a type annotation survives to run time.

The interface vanished entirely: an interface is a compile-time shape, not an object. So you cannot test a type with `typeof` or `instanceof`, and data crossing the boundary (JSON from a server, a form field, `localStorage`) is NOT checked. Validate it yourself.

Why bother, then? Because the check happens BEFORE you ship: a typo, a wrong argument order, or a forgotten null is a red squiggle in the editor instead of a bug in production. TypeScript is a superset: every valid `.js` file is already valid `.ts`. In this course we run `.ts` straight through `tsx`, which strips the types without type-checking; `tsc --noEmit` does the checking.
